

ISOMORPHISM CLASSES OF ELLIPTIC CURVES OVER A FINITE FIELD IN SOME THIN FAMILIES

JAVIER CILLERUELO, IGOR E. SHPARLINSKI, AND ANA ZUMALACÁRREGUI

ABSTRACT. For a prime p a given square box, \mathfrak{B} , we consider all elliptic curves $E_{r,s} : Y^2 = X^3 + rX + s$ defined over a field \mathbb{F}_p of p elements with coefficients $(r, s) \in \mathfrak{B}$. We obtain a nontrivial upper bound for the number of such curves which are isomorphic to a given one over \mathbb{F}_p , in terms of the size of \mathfrak{B} . We also give an optimal lower bound on the number of distinct isomorphic classes represented.

1. BACKGROUND AND NOTATION

For a prime p we consider the family of elliptic curves $E_{a,b}$ given by a Weierstrass equation

$$E_{a,b} : Y^2 = X^3 + aX + b$$

over the finite field \mathbb{F}_p of p elements, where

$$(1) \quad (a, b) \in \mathbb{F}_p^2, \quad 4a^3 + 27b^2 \neq 0.$$

Recall that for a large enough prime, say $p > 3$, it is well known that every elliptic curve over \mathbb{F}_p has a representation of this type, see [13] for a background on elliptic curves. Thus, from now on, curves are considered as parameterized by their coefficients.

Two curves $E_{r,s}$ and $E_{u,v}$ are isomorphic if for some $t \in \mathbb{F}_p^*$ we have

$$(2) \quad rt^4 \equiv u \pmod{p} \quad \text{and} \quad st^6 \equiv v \pmod{p}.$$

There are several works which count the number of curves $E_{r,s}$ isomorphic to a given curve $E_{a,b}$, with coefficients r, s lying in certain box $(r, s) \in [R+1, R+K] \times [S+1, S+L]$, see [2, 8]. In particular, for

$$(3) \quad KL \geq p^{3/2+\varepsilon} \quad \text{and} \quad \min\{K, L\} \geq p^{1/2+\varepsilon}$$

with some fixed $\varepsilon > 0$, using exponential sum techniques, Fouvry and Murty [8] have obtained an asymptotic formula for every pair (a, b) with (1). In [2], using bounds of multiplicative character sums, for almost all (a, b) with (1), this condition (3) has been relaxed to

$$KL \geq p^{1+\varepsilon} \quad \text{and} \quad \min\{K, L\} \geq p^{1/4+\varepsilon}.$$

Furthermore, it is shown in [2], that for

$$KL \geq p^{1+\varepsilon} \quad \text{and} \quad \min\{K, L\} \geq p^{1/4e^{1/2}+\varepsilon}$$

one can get a lower bound with the right order of magnitude (again for almost all (a, b) with (1)). On average over p , such results are established for even smaller boxes, see [2].

Here we consider squared boxes, much smaller than the previous ones, given by

$$(4) \quad \mathfrak{B} = [R + 1, R + M] \times [S + 1, S + M] \subseteq \mathbb{F}_p \times \mathbb{F}_p,$$

for a prime p and some nonnegative integers R, S, M satisfying

$$(5) \quad R, S \geq 0, M \geq 1 \quad \text{and} \quad R + M, S + M < p.$$

We use $|\mathfrak{B}|$ to denote the area of \mathfrak{B} , that is,

$$|\mathfrak{B}| = M^2.$$

We are interested in understanding how isomorphism classes are distributed in such small boxes \mathfrak{B} . Among all curves $E_{r,s}$, parameterized by coefficients $(r, s) \in \mathfrak{B}$, we study, in first place, the number of isomorphism classes which are represented and, finally, the number of curves lying in a given isomorphism class.

Clearly, the existence of an isomorphism between $E_{r,s}$ and $E_{s,t}$, see (2), imply that

$$(6) \quad r^3 v^2 \equiv u^3 s^2 \pmod{p}.$$

We denote by $T(\mathfrak{B})$ the number of solutions to (6) with $(r, s), (u, v) \in \mathfrak{B}$. Furthermore, for $\lambda \in \mathbb{F}_p$, we denote by $N_\lambda(\mathfrak{B})$ the number of solutions to the congruence

$$r^3 \equiv \lambda s^2 \pmod{p}, \quad (r, s) \in \mathfrak{B}.$$

We use the bounds of character sums detailed in section 2 to obtain an upper bound on $T(\mathfrak{B})$. From this estimate we derive an almost optimal lower bound for the number $I(\mathfrak{B})$, of nonisomorphic curves with coefficients in \mathfrak{B} , of the form

$$(7) \quad I(\mathfrak{B}) \geq \min \left\{ (1 + o(1))p, |\mathfrak{B}|^{1+o(1)} \right\},$$

see Corollary 6 below for a more precise formulation.

Clearly, the bound (7) is quite tight as we have the trivial upper bound

$$I(\mathfrak{B}) \leq \min \{2p + O(1), |\mathfrak{B}|\},$$

since it is well known [12] that the number of isomorphism classes of elliptic curves in \mathbb{F}_p is $2p + O(1)$.

Finally, we exploit the method of [5], based on the ideas of [4] (see also [15]), to obtain in section 5 upper bounds on $N_\lambda(\mathfrak{B})$, which, in particular, imply upper bounds for the number of elliptic curves $E_{r,s}$ with coefficients $(r, s) \in \mathfrak{B}$ that fall in the same isomorphism class.

Throughout the paper, any implied constants in the symbols O , \ll and \gg are absolute otherwise. We recall that the notations $U = O(V)$, $U \ll V$ and $V \gg U$ are all equivalent to the statement that the inequality $|U| \leq cV$ holds with some constant $c > 0$.

2. CHARACTER SUMS

Let \mathcal{X} be the set of all multiplicative characters modulo p and let $\mathcal{X}^* = \mathcal{X} \setminus \{\chi_0\}$ be the set of nonprincipal characters.

We recall the Pólya-Vinogradov bound, see [11, Theorem 12.5].

Lemma 1. *For arbitrary integers W and Z , with $0 \leq W < W + Z < p$, the bound*

$$\max_{\chi \in \mathcal{X}^*} \left| \sum_{z=W+1}^{W+Z} \chi(z) \right| \ll p^{1/2} \log p$$

holds.

We recall that Garaev and García [9], improving a result of Ayyad, Cochrane and Zheng [1] (see also [6]), have shown that for any integers W and Z

$$(8) \quad \sum_{\chi \in \mathcal{X}^*} \left| \sum_{z=W+1}^{W+Z} \chi(z) \right|^4 \ll pZ^2 \left(\log p + (\log(Z^2/p))^2 \right).$$

Note that for any fixed $\varepsilon > 0$, if $Z \geq p^\varepsilon$ the right hand side of (8) is of the form $pZ^{2+o(1)}$. However for small values of Z , namely for $Z \ll (\log p)^{1/2}$, the bound (8) is trivial. We now combine (8) with a result of [4] to get the bound $pZ^{2+o(1)}$ for any Z .

Lemma 2. *For arbitrary integers W and Z , with $0 \leq W < W + Z < p$, the bound*

$$\sum_{\chi \in \mathcal{X}^*} \left| \sum_{z=W+1}^{W+Z} \chi(z) \right|^4 \ll pZ^{2+o(1)}$$

holds.

Proof. We can assume that $Z \leq p^{1/4}$ since otherwise, as we have noticed before, the bound (8) implies the desired result. Now, using that for any integer z with $\gcd(z, p) = 1$, for the complex conjugated character $\bar{\chi}$ we have

$$\bar{\chi}(z) = \chi(z^{-1}),$$

we derive,

$$\sum_{\chi \in \mathcal{X}_0} \left| \sum_{z=W+1}^{W+Z} \chi(z) \right|^4 \leq \sum_{\chi \in \mathcal{X}} \left| \sum_{z=W+1}^{W+Z} \chi(z) \right|^4 = \sum_{z_1, z_2, z_3, z_4=W+1}^{W+Z} \sum_{\chi \in \mathcal{X}} \chi(z_1 z_2 z_3^{-1} z_4^{-1}).$$

Thus, using the orthogonality of characters we obtain

$$\sum_{\chi \in \mathcal{X}^*} \left| \sum_{z=W+1}^{W+Z} \chi(z) \right|^4 \leq pJ,$$

where J is number of solutions to the congruence

$$z_1 z_2 \equiv z_3 z_4 \pmod{p}, \quad z_1, z_2, z_3, z_4 \in [W + 1, W + Z].$$

By [4, Theorem 1], for any $\lambda \not\equiv 0 \pmod{p}$ the congruence

$$z_1 z_2 \equiv \lambda \pmod{p}, \quad z_1, z_2 \in [W + 1, W + Z]$$

has $Z^{o(1)}$ solutions, provided that $Z \leq p^{1/4}$. Therefore $J \leq Z^{2+o(1)}$ and the result follows. \square

3. SMALL POINTS ON SOME HYPERSURFACES

For the number of points in very small boxes we can get a better bound by using the following estimate of Bombieri and Pila [3] on the number of integral points on polynomial curves.

Lemma 3. *Let \mathcal{C} be an absolutely irreducible curve of degree $d \geq 2$ and $H \geq \exp(d^6)$. Then the number of integral points on \mathcal{C} and inside of a square $[0, H] \times [0, H]$ does not exceed $H^{1/d} \exp(12\sqrt{d} \log H \log \log H)$.*

For an integer a we used $\|a\|_p$ to denote the smallest by absolute value residue of a modulo p , that is

$$\|a\|_p = \min_{k \in \mathbb{Z}} |a - kp|.$$

By the Dirichlet pigeon-hole principle we easily obtain the following result.

Lemma 4. *For any real numbers T_1, \dots, T_s with*

$$p > T_1, \dots, T_s \geq 1 \quad \text{and} \quad T_1 \cdots T_s > p^{s-1}$$

and any integers a_1, \dots, a_s there exists an integer t with $\gcd(t, p) = 1$ and such that

$$\|a_i t\|_p \ll T_i, \quad i = 1, \dots, s.$$

4. BOUND ON $T(\mathfrak{B})$

In fact we consider a more general quantity, that is for given positive integers i, j we bound the number $T_{i,j}(\mathfrak{B})$ of solutions to the equation

$$(9) \quad r^i v^j \equiv u^i s^j \pmod{p}$$

with $(r, s), (u, v) \in \mathfrak{B}$. Thus, in this setting, $T(\mathfrak{B}) = T_{3,2}(\mathfrak{B})$.

Theorem 5. *For any prime p and any box \mathfrak{B} given by (4) and satisfying (5) we have,*

$$T_{i,j}(\mathfrak{B}) = d \frac{|\mathfrak{B}|^2}{p-1} + O\left(|\mathfrak{B}| p^{o(1)}\right)$$

as $|\mathfrak{B}| \rightarrow \infty$, where $d = \gcd(i, j, p-1)$.

Proof. Using the orthogonality of characters, we write the the number of solutions to (9) with $(r, s), (u, v) \in \mathfrak{B}$ as

$$\begin{aligned} T_{i,j}(\mathfrak{B}) &= \sum_{r,u=R+1}^{R+M} \sum_{s,v=S+1}^{R+M} \frac{1}{p-1} \sum_{\chi \in \mathcal{X}} \chi((r/u)^i (v/s)^j) \\ &= \frac{1}{p-1} \sum_{\chi \in \mathcal{X}} \left| \sum_{r=R+1}^{R+M} \chi^i(r) \right|^2 \left| \sum_{s=S+1}^{S+M} \chi^j(s) \right|^2. \end{aligned}$$

The contribution to the above sum from d characters $\chi \in \mathcal{X}$ with $\chi^i = \chi^j = \chi_0$ is $dM^4/(p-1)$.

Using Lemma 1, we see that the contribution to the above sum from at most i characters $\chi \in \mathcal{X}$ with $\chi^i = \chi_0$ and $\chi^j \neq \chi_0$ is bounded by

$$\frac{M^2}{p-1} \sum_{\substack{\chi \in \mathcal{X} \\ \chi^i = \chi_0}} \left| \sum_{s=S+1}^{S+M} \chi^j(s) \right|^2 \ll M^2 (\log p)^2$$

The contribution from the characters $\chi \in \mathcal{X}$ with $\chi^j = \chi_0$ and $\chi^i \neq \chi_0$ can be estimated similarly as $O(M^2 \log p)$.

Therefore

$$(10) \quad T_{i,j}(R, S; M) = d \frac{M^4}{p-1} + O(M^2 (\log p)^2 + W)$$

where

$$W = \frac{1}{(p-1)^2} \sum_{\substack{\chi \in \mathcal{X} \\ \chi^i, \chi^j \neq \chi_0}} \left| \sum_{r=R+1}^{R+M} \chi^i(r) \right|^2 \left| \sum_{s=S+1}^{S+M} \chi^j(s) \right|^2.$$

Using the Cauchy inequality, we derive

$$(11) \quad W^2 \leq \frac{1}{(p-1)^2} \sum_{\substack{\chi \in \mathcal{X} \\ \chi^i, \chi^j \neq \chi_0}} \left| \sum_{r=R+1}^{R+M} \chi^i(r) \right|^4 \times \sum_{\substack{\chi \in \mathcal{X} \\ \chi^i, \chi^j \neq \chi_0}} \left| \sum_{s=S+1}^{S+M} \chi^j(s) \right|^4.$$

When χ runs through \mathcal{X} the power χ^h represents any other character in \mathcal{X} no more than h times. Thus

$$\sum_{\substack{\chi \in \mathcal{X} \\ \chi^i, \chi^j \neq \chi_0}} \left| \sum_{r=R+1}^{R+M} \chi^i(r) \right|^4 \ll \sum_{\chi \in \mathcal{X}^*} \left| \sum_{r=R+1}^{R+M} \chi^i(r) \right|^4$$

and similarly for the second double sums over s .

Combining the above bounds with inequality (11), applying Lemma 2, and then using (10), we conclude the proof. \square

Corollary 6. *For any prime p and any box \mathfrak{B} given by (4) and satisfying (5) we have,*

$$I(\mathfrak{B}) \geq \min \left\{ p(1 + O(|\mathfrak{B}|^{-1+o(1)}p)), |\mathfrak{B}|^{1+o(1)} \right\}$$

as $|\mathfrak{B}| \rightarrow \infty$.

Proof. Let $\Gamma = \{r^3/s^2 : (r, s) \in \mathfrak{B}\}$, we recall that

$$N_\lambda(\mathfrak{B}) = |\{(r, s) \in \mathfrak{B} : r^3/s^2 = \lambda\}|.$$

Using the Cauchy inequality we derive

$$|\mathfrak{B}|^2 = \left(\sum_{\lambda \in \Gamma} N_\lambda(\mathfrak{B}) \right)^2 \leq |\Gamma| \sum_{\lambda} N_\lambda^2(\mathfrak{B}) \leq I(\mathfrak{B}) T_{3,2}(\mathfrak{B}).$$

We conclude the proof by estimating $T_{3,2}(\mathfrak{B})$ with Theorem 5. \square

It is easy to see that Corollary 6 implies the bound (7).

5. BOUND ON $N_\lambda(\mathfrak{B})$

It is easy to see that for $\lambda \in \mathbb{F}_p^*$ the curve $X^3 = \lambda Y^2$ is absolutely irreducible. So general bounds on the number of points on a curve in a given box (see, for example, [14]) immediately imply that

$$(12) \quad N_\lambda(\mathfrak{B}) = \frac{|\mathfrak{B}|}{p} + O\left(p^{1/2}(\log p)^2\right),$$

which gives a trivial upper bound when $|\mathfrak{B}| \ll p^{1/2} \log p$.

We are now ready to derive a nontrivial upper bound on $N_\lambda(\mathfrak{B})$ for smaller values of M .

Lemma 7. *For any prime p , any box \mathfrak{B} , given by (4) and with $1 \leq |\mathfrak{B}| \leq p^{2/9}$, satisfying (5) and $\lambda \in \mathbb{F}_p^*$ we have*

$$N_\lambda(\mathfrak{B}) \leq |\mathfrak{B}|^{1/6+o(1)}$$

as $|B| \rightarrow \infty$.

Proof. We have to estimate the number of solutions to

$$(R+x)^3 \equiv \lambda(S+y)^2 \pmod{p},$$

with $1 \leq x, y \leq M$, which is equivalent to the congruence

$$(13) \quad x^3 + 3Rx^2 + 3R^2x - \lambda y^2 - 2\lambda Sy \equiv \lambda S^2 - R^3 \pmod{p}.$$

For any $T \leq p^{1/4}/M^{1/2}$, we can apply Lemma 4 to

$$a_1 = 1, \quad a_2 = 3R, \quad a_3 = 3R^2, \quad a_4 = -\lambda, \quad a_5 = -2\lambda S$$

and

$$T_1 = T^4 M^2, \quad T_2 = T_4 = p/(TM), \quad T_3 = T_5 = p/T,$$

and conclude that there exists $|t| \leq T^4 M^2$ such that

$$\|3Rt\|_p \leq p/(TM), \quad \|\lambda t\|_p \leq p/(TM), \quad \|3R^2 t\|_p \leq p/T, \quad \|2\lambda S t\|_p \leq p/T.$$

Thus, by multiplying both sides of the congruence (13) by t , we can replace the congruence(13) with the following equation over \mathbb{Z} :

$$(14) \quad A_1 x^3 + A_2 x^2 + A_3 x + A_4 y^2 + A_5 y + A_6 = pz,$$

where

$$|A_1| \leq T^4 M^2, \quad |A_2|, |A_4| \leq p/(TM), \quad |A_3|, |A_5| \leq p/T, \quad |A_6| \leq p/2.$$

Since, for $0 \leq x, y \leq M$, the left hand side of the equation (14) is bounded by $T^4 M^5 + 4pM/T + p/2$, it follows that

$$|z| \ll \frac{T^4 M^5}{p} + \frac{4M}{T} + 1.$$

The choice $T \sim p^{1/5}/M^{4/5}$ leads us to the bound

$$|z| \ll M^{9/5} p^{-1/5} + 1 \ll 1$$

since $M = |\mathfrak{B}|^{1/2} \leq p^{1/9}$.

We note that the polynomial $A_1 X^3 + A_2 X^2 + A_3 X + A_4 Y^2 + A_5 Y + A_6$ on left hand side of (14) is absolutely irreducible. Indeed, it is obtained from $X^3 - \lambda Y^2$ (which is an absolutely irreducible polynomial) by a nontrivial modulo p affine transformation. Therefore, for every integer z , the polynomial $A_1 X^3 + A_2 X^2 + A_3 X + A_4 Y^2 + A_5 Y + A_6 - pz$ is also absolutely irreducible (as its reduction modulo p is absolutely irreducible modulo p).

Thus, for each z in the previous range, equation (14) corresponds to an absolutely irreducible curve of degree 3 which, by Lemma 3, has at most $M^{1/3+o(1)}$ points lying in $[0, M]^2$. Therefore, the number of solutions in the original equation is bounded by $M^{1/3+o(1)} = |\mathfrak{B}|^{1/6+o(1)}$. \square

The family of curves $E_{r,s}$ with $(r, s) = (t^2, t^3)$, $1 \leq t \leq |\mathfrak{B}|^{1/6}$, shows that the exponent $1/6$ in the bound of Lemma 7 cannot be improved, which means that we cannot obtain a general bound stronger than $N_\lambda(\mathfrak{B}) = O(|\mathfrak{B}|^{1/6})$.

Clearly the argument used in the proof of Lemma 7 works for large values of $|\mathfrak{B}|$. In particular, for $|\mathfrak{B}| > p^{2/9}$, it leads to the bound $N_\lambda(\mathfrak{B}) \ll |\mathfrak{B}|^{16/15+o(1)}p^{-1/5}$ which is nontrivial for $|\mathfrak{B}| \leq p^{6/17}$.

However, using a modification of this argument we can obtain a stronger bound which is nontrivial for $p^{2/9} < |\mathfrak{B}| \leq p^{2/5}$:

Lemma 8. *For any prime p , any box \mathfrak{B} , given by (4) with $p^{2/9} < |\mathfrak{B}| \leq p^{2/5}$, satisfying (5) and $\lambda \in \mathbb{F}_p^*$ we have*

$$N_\lambda(\mathfrak{B}) \leq |\mathfrak{B}|^{11/12+o(1)}p^{-1/6}$$

as $|\mathfrak{B}| \rightarrow \infty$.

Proof. Let $K = \lfloor p^{1/6}/M^{1/2} \rfloor$ and observe that we have $1 \leq K \leq M$ when $p^{2/9} < |\mathfrak{B}| = M^2$. Also observe that one could cover \mathfrak{B} with $J = O(M/K)$ rectangles of the form $[R_j + 1, R_j + K] \times [S + 1, S + M]$, $j = 1, \dots, J$. Then, the equation in each rectangle can be written as

$$(15) \quad x^3 + 3R_jx^2 + 3R_j^2x - \lambda y^2 - 2\lambda S y \equiv \lambda S^2 - R_j^3 \pmod{p}$$

with $1 \leq x \leq K$ and $1 \leq y \leq M$.

To estimate the number of solutions to (15), we set

$$T_1 = p^{1/2}M^{3/2}, \quad T_2 = p^{2/3}M, \quad T_3 = p^{5/6}M^{1/2}, \quad T_4 = p/M^2, \quad T_5 = p/M.$$

and apply, once more, Lemma 4 where a_i are the coefficients of x, y in (15). Hence, as in the proof of Lemma 7, we obtain an equivalent equation over \mathbb{Z} :

$$(16) \quad A_1x^3 + A_2x^2 + A_3x + A_4y^2 + A_5y + A_6 = pz,$$

where $|A_i| \leq T_i$ for $i = 1, \dots, 5$ and $|A_6| \leq p/2$. The left hand side of (16) is bounded by

$$\begin{aligned} & |A_1K^3 + A_2K^2 + A_3K + A_4M^2 + A_5M + A_6| \\ & \leq p^{1/2}M^{3/2} \left(\frac{p^{1/6}}{M^{1/2}} \right)^3 + p^{2/3}M \left(\frac{p^{1/6}}{M^{1/2}} \right)^2 + p^{5/6}M^{1/2} \frac{p^{1/6}}{M^{1/2}} \\ & \quad + \frac{p}{M^2}M^2 + \frac{p}{M^2}M + p/2 \\ & = 5.5p. \end{aligned}$$

Thus, z can take at most 11 values. As we have seen in the proof of Lemma 7, the polynomial on the left hand side of (16) is absolutely irreducible. Therefore, Lemma 3 implies that, for each value of z , equation (16) has at most $M^{1/3+o(1)}$ solutions. Summing over all rectangles we finally obtain that the original congruence has at most

$$(M/K)M^{1/3+o(1)} = M^{11/6+o(1)}p^{-1/6} = |\mathfrak{B}|^{11/12+o(1)}p^{-1/6}$$

solutions. □

Combining (12) with Lemmas 7 and 8, we obtain:

Theorem 9. *For any prime p , box \mathfrak{B} given by (4) and satisfying (5) and $\lambda \in \mathbb{F}_p^*$ we have,*

$$N_\lambda(\mathfrak{B}) \ll |\mathfrak{B}|^{o(1)} \begin{cases} |\mathfrak{B}|^{1/6}, & \text{if } |\mathfrak{B}| < p^{2/9}, \\ |\mathfrak{B}|^{11/12} p^{-1/6}, & \text{if } p^{2/9} \leq |\mathfrak{B}| < p^{2/5}, \\ p^{1/2}, & \text{if } p \leq |\mathfrak{B}| < p^{3/2}, \\ |\mathfrak{B}| p^{-1}, & \text{if } p^{3/2} \leq |\mathfrak{B}| < p^2, \end{cases}$$

as $|\mathfrak{B}| \rightarrow \infty$.

We note that unfortunately in the range $p^{2/5} \leq |\mathfrak{B}| < p$ we could not find any nontrivial estimate.

6. COMMENTS AND OPEN PROBLEMS

Note that Theorem 5 can be easily extended to coefficients (r, s) that belong to rectangles $[R + 1, R + K] \times [S + 1, S + L]$ rather than squares (the bound (12) also holds for such rectangles).

As we have mentioned the exponent $1/6$ in the bound of Lemma 7 cannot be improved, however the range $|\mathfrak{B}| \leq p^{2/9}$ can possibly be extended. As the first step towards this, the following question has to be answered:

Problem 1. *Let E be an elliptic given by a Weierstrass equation*

$$y^2 + a_1xy + a_3y = x^3 + a_2x^2 + a_4x + a_6, \quad a_i \in \mathbb{Z},$$

such that all the coefficients are $M^{o(1)}$. Is it true that the number of integer points $(x, y) \in [0, M] \times [0, M]$ on E is $M^{o(1)}$?

We refer to [7, 10] for some bounds on the number of points on elliptic curves in boxes.

As we have noticed in Section 5 we have not found nontrivial bounds on $N_\lambda(\mathfrak{B})$ for $p^{2/5} \leq |\mathfrak{B}| < p$. It is certainly interesting to close this gap.

Problem 2. *Is it true that $N_\lambda(\mathfrak{B}) = o(|\mathfrak{B}|^{1/2})$ for all $|\mathfrak{B}| = o(p^2)$?*

Finally, it is also natural to expect that the term $|\mathfrak{B}|^{o(1)}$ can be removed from the result obtained in Corollary 6.

Problem 3. *Is it true that $I(\mathfrak{B}) \gg \min\{p, |\mathfrak{B}|\}$?*

ACKNOWLEDGEMENT

The authors are grateful to Moubariz Garaev and Joe Silverman for their comments.

This work started during a very pleasant visit by I. S. to the Universidad Autónoma de Madrid; the support and hospitality of this institution are gratefully acknowledged.

During the preparation of this paper, J.C. was supported by Grant MTM 2008-03880 of MICINN (Spain), I. S. was supported in part by ARC grant DP1092835 (Australia) and by NRF Grant CRP2-2007-03 (Singapore), and A. Z. was supported by Departamento de Matemáticas, UAM (Spain).
